

ClawVAPT

Telegram-first multi-agent VAPT assistant

Authorized security triage from chat: ownership verification, scope lock, QRIS credits, safe scanners, and report-ready output.

Built MVP

Agentic

Safety-first

Demo-ready

Jury goal: show a real product loop, not just a scanner wrapper.

PROBLEM

Security checks are still too hard for small teams

Raw scanners are powerful, but the real workflow breaks around authorization, scope, payment, evidence, and reports.

Cost barrier

Early-stage teams skip VAPT because services feel expensive or slow.

Unsafe flow

A scanner without ownership proof and scope control can hit the wrong target.

Messy output

Findings need normalization, redaction, remediation, and proof.

No workflow

Operators stitch together chat, scanners, payments, logs, and PDFs manually.

Opportunity: make the first security check cheap, guided, auditable, and safe by default.

A complete VAPT workflow inside Telegram

ClawVAPT turns chat commands into a controlled backend workflow: verify, scan, normalize, redact, and deliver reports.

- Web target scans require ownership proof, explicit approval, and locked scope.
- Public GitHub repo scans run as a standalone low-friction path.
- PDF, JSON, and manual-review outputs are delivered back to Telegram.

The judge can test the core loop in minutes

The repo is structured around demo artifacts, commands, logs, reports, and acceptance criteria - ideal for hackathon judging.

Web target

Public repo

Payment

Judge narrative: every command proves one part of the product - authorization, execution, monetization, or reporting.

One bot, three specialized agent workspaces

MainOrchestrator coordinates deterministic gates, state, scanner adapters, payment checks, and report delivery.

The moat is not more exploits. It is safe execution.

ClawVAPT makes consent, scope, and redaction first-class product controls instead of afterthoughts.

- | | | |
|----|--------------------------|--|
| 01 | Ownership proof | HTTP/DNS challenge before web scans |
| 02 | Scope lock | Host remains fixed during active testing |
| 03 | Explicit approval | Active scan and Nmap require user agreement |
| 04 | Secret redaction | No raw secrets in chat, reports, logs, or README |
| 05 | Audit trail | JSONL events prove what ran and why |

Why it matters to judges: it demonstrates responsible security automation, not an unsafe offensive toy.

A deployable MVP with real engineering depth

The repo includes source, docs, tests, CI/CD, runbook, demo checklist, reports, and security policy.

Scanner adapters

security tools

Scanners are optional adapters; the product value is orchestration, safety gates, evidence handling, and report generation.

Built to score on creativity, usefulness, and execution

ClawVAPT is a security product workflow wrapped in a friendly Telegram-native interface.

- 1 Creative agent experience**

No dashboard needed: users start, pay, approve, and receive reports in chat.
- 2 Real-world use case**

Initial VAPT for freelancers, student teams, indie devs, UMKM, and small dev teams.
- 3 Autonomous workflow**

Stateful multi-agent loop makes decisions and calls tools after gate checks.
- 4 Responsible design**

Authorization and scope are enforced before active scans run.
- 5 Demo evidence**

Reports, logs, docs, tests, Docker/PM2 flow, and acceptance checklist.

A practical wedge into affordable security automation

Credit-gated scans make security checks accessible while proving repeat-use monetization.

QRIS

top-up in Telegram

-
- Beachhead: public repo and verified web target triage.
 - Expansion: agencies, teams, dashboard UI, private repos.
 - Long-term: continuous monitoring and retest evidence packs.

From hackathon MVP to security copilot for small teams

The next phase converts one-off checks into a continuous, safe, report-ready security workflow.

Ask

Pilot users, security mentors, and integration partners to validate scans, reports, and remediation workflows with real teams.

ClawVAPT

Cute claws. Real guardrails. Report-ready security.
